

# Enabling Compression

In certain scenarios (especially over slow Internet connections), enabling compression can improve application performance.

To enable compression, the HTTP Configuration File (**/www/profoundui/conf/httpd.conf**) must be modified. At the top of the file, add this line:

```
LoadModule deflate_module /QSYS.LIB/QHTTPSVR.LIB/QZSRCORE.SRVPGM
```

Then, add the following lines above the existing DirectoryMatch directives:

```
<Location / >  
  SetOutputFilter DEFLATE  
</Location>
```

The HTTP Server must then be restarted. See [here](#).
